LEADERSHIP BRIEFING

# CEQ AI Call Audit Platform: Executive Summary

What I built, what I learned, what it costs, and what I need to move it forward

**~$0.035**
average AI cost per audited call (measured in my test runs)

**54**
rostered analysts I mapped to Genesys automatically

**3**
AI vendors in my fallback chain, so one outage does not stop audits

**100%**
of AI results are drafts confirmed by a human reviewer

### What it does

- Finds completed Service Desk calls automatically.
- Turns the recording into a written transcript.
- Finds the matching ServiceNow ticket and the right support procedure.
- Scores the call against the CEQ standard and produces a review-ready report.

### Why it matters

- Removes manual searching for recordings and tickets.
- Gives faster, more consistent feedback to analysts.
- Checks the ticket documentation behind every call.
- Low running cost: roughly $9 to $59 per 1,000 audits on the models I tested.

### Where I am

- I have a working prototype running in Matcha Design Studio.
- I validated it with synthetic test calls, so no customer data was required.
- It cannot move to the new MatchaOS platform as-is; a hosting decision is needed.
- Governance, privacy and accuracy sign-off are still required before production.

**Bottom line:** the approach works and is inexpensive to run. Before it is used for coaching or performance decisions, I need a production hosting decision, governance approval, and proof that the AI scores agree with experienced human auditors.

RESEARCH & DEVELOPMENT

# What I Built and What I Learned

The key design choices I made to get the solution working within existing systems

### Built on existing tools

- I developed it as custom building blocks in Matcha Design Studio.
- Each block does one job: retrieve, transcribe, match, evaluate, report.

### Connected to Genesys

- For testing I use temporary access credentials.
- Permanent read-only production access has been requested; I am waiting for the credentials.

### No changes to call routing

- I did not have access to change Genesys call flows, so I designed the system to look up calls by analyst instead.
- I matched all 54 rostered analysts to their Genesys accounts.

### Automatic call selection

- Completed calls for a chosen day are pulled automatically.
- I added a daily limit per analyst to control audit volume.

### No duplicate audits

- Every audit is tied to a unique call ID.
- Work already done is reused instead of repeated, saving time and cost.

### Handling long calls

- The platform cuts off requests after about 100 seconds, and long calls take longer than that to transcribe.
- I moved transcription to run in the background, with results collected when ready.

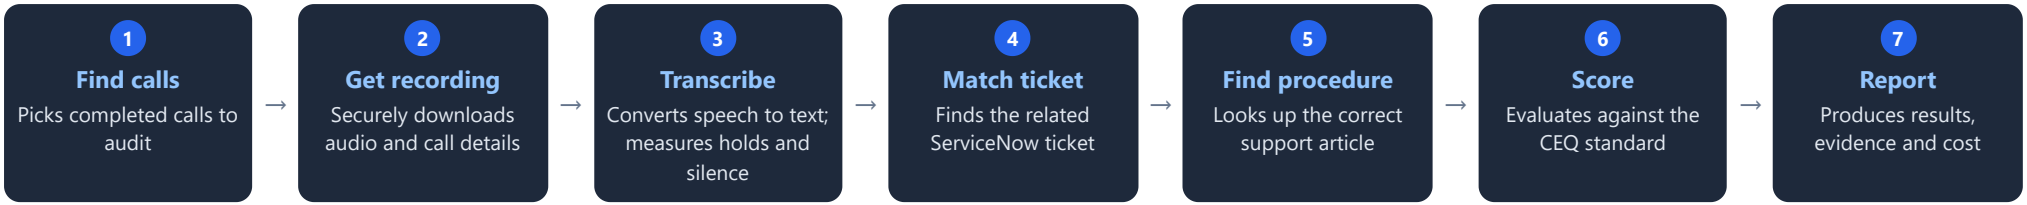

**Platform change (feedback I received from the Matcha team):** MatchaOS launches in the first week of November with ready-made apps, better Excel support and built-in assistance. Existing missions and Design Studio work will be migrated. However, because I built the Call Audit flow on custom code, **it cannot be moved to the new Flow Builder in its current form.** The options offered are to **self-host Langflow** (the closest equivalent) or to **consult the Nebula team** on productionising it.

**My recommendation:** treat the current build as a proven prototype and assess a self-hosted Langflow deployment, with Nebula's input, as the production route. Software dependencies, security and licensing must be approved as part of that move.

HOW IT WORKS

# From Phone Call to Audit Report in Seven Steps

Each step runs automatically; a human reviewer confirms the final result

| STEP | WHAT HAPPENS | BUSINESS VALUE |
|---|---|---|
| **1. Find calls** | The Dispatcher checks Genesys for completed calls by rostered analysts and starts an audit for each. | No manual call selection or scheduling. |
| **2. Get recording** | Downloads the call recording and details such as start time, queue and hold periods. | No manual searching for recordings. |
| **3. Transcribe** | Converts the recording into a time-stamped conversation and flags holds, silence and unclear words. | Reviewers read instead of listening to whole calls. |
| **4. Match ticket** | Uses clear rules first (ticket number spoken, analyst, time, caller details), then AI to confirm the best match. | Accurate link between the call and its documentation. |
| **5. Find procedure** | Retrieves the client-specific support article. Only high-confidence matches are enforced; others are advisory. | Calls are judged against the right procedure, not a guess. |
| **6. Score** | AI scores the call against the CEQ framework with timestamped evidence, using measured facts it may not contradict. | Faster, more consistent scoring. |
| **7. Report** | Recalculates the score, applies the 96% target, flags items for manager review, and produces the report and cost summary. | Review-ready output with a full evidence trail. |

**Safeguards I built into every AI request:** patient information is screened out first; the request falls back across three AI vendors if one fails; slow or unusable answers are retried or rejected; and a log records which model answered and what it cost.

DATA HANDLING

# How Audit Data Is Stored and Removed

I designed the solution to keep data only as long as needed to complete the audit; a few items are still open

| DATA | WHAT HAPPENS TO IT | STATUS |
|---|---|---|
| **Call recordings** | Deleted automatically as soon as transcription finishes, even if transcription fails. | Automatic |
| **Transcripts (temporary copy)** | Kept up to 24 hours to avoid repeat work, then removed. Removal happens the next time the system runs, so copies can last longer during quiet periods. | Partly automatic |
| **ServiceNow ticket export** | Read in memory only, never saved locally; replaced by each new export. | Automatic |
| **AI requests and answers** | I configured the AI missions not to keep conversation history. | Configured |
| **HTML audit reports** | Deleted automatically after 7 days. | Automatic |
| **Cost and routing logs** | Record the model used and the cost only. If patient information is detected, only the type is logged, never the content. | No call content |
| **Test recordings (manual uploads)** | I keep these on purpose so tests can be repeated; they must be removed manually. | Manual |
| **Final audit results** | Kept as the official audit record. I am yet to build a sharepoint list or site need GRAPH API or alternative secure solutions to pass on the results. | Pending |
| **Platform run history** | How long the Matcha platform keeps run history has not yet been confirmed to me. | Open item |

### Already in place

- Recordings, reports and temporary files are removed automatically.
- Ticket data is never written to disk.
- The AI missions do not keep conversation history.

### What I will close before production

- Confirm platform run-history retention with the Matcha team.
- Add a scheduled clean-up so transcript removal does not depend on new activity.
- Get a retention period for audit results approved.

PATIENT INFORMATION PROTECTION

# How Sensitive Information Is Handled Today

My honest view of current protection, based on what I have built and what is running now

**Active: screening before AI**

- Every request is checked for patient information before it reaches an AI model.
- Flagged sentences are removed, or the call is sent to manual review.

**Built, not switched on: credential removal**

- Passwords and codes spoken on calls are detected and flagged.
- I left removal off because it also deletes ticket numbers needed for matching.

**Limits of current protection**

- Detection depends on how things are said on the call.
- Temporary transcripts are stored unredacted for up to 24 hours.

| INFORMATION | CURRENT HANDLING | PROTECTION LEVEL |
|---|---|---|
| Medical record numbers, SSNs | Caught by recognised terms and number formats. | Reliable |
| Patient names, dates of birth, clinical details | Caught when mentioned with words like "patient" or "date of birth"; may be missed otherwise. | Partial |
| Passwords, verification codes, one-time passwords | Detected and flagged for the reviewer, but not removed. | Flagged only |
| Employee IDs | Kept on purpose: used to confirm caller identity and match tickets. | Kept by design |
| Staff names, emails, phone numbers, ticket numbers, departments | Not patient information; kept to identify the analyst, match tickets and find the right procedure. | Not PHI |

**Decision I need:** Security, Privacy and Governance to review and approve this classification, the detection coverage, and whether to enable credential removal before production use. I am limited to experimenting with non-PHI data, which is why I conducted testing using synthetic calls

RUNNING COST

# AI Model Cost Comparison

AI cost is small; in my view the model choice should be driven by accuracy, not price

| AI MODEL | COST PER AUDIT | PER 1,000 AUDITS | FIT | SUMMARY |
|---|---|---|---|---|
| **GPT-5.4 Nano** (tested) | $0.0089 | ~$9 | Strong candidate | Cheapest I tested; ran without errors. Accuracy not yet compared with human auditors. |
| **Claude Haiku 4.5** (tested) | $0.0386 | ~$39 | Good fallback | Reliable and found the correct ticket in my testing; higher cost. |
| **Gemini 3.1 Flash Lite** (tested) | $0.0587 | ~$59 | Proven, pricier | Worked where older Gemini models failed; most expensive of the three I tested. |
| Gemini 3 Flash | ~$0.022 | ~$22 | Strong candidate | Low cost with strong capability; needs accuracy testing. |
| Claude Haiku 5.5 | ~$0.019 | ~$19 | Strong candidate | Good balance of price and capability; needs accuracy testing. |
| Gemini 2.5 Flash Lite | ~$0.0034 | ~$3 | Not suitable | Cheapest, but unreliable at ticket matching in my testing. |
| Claude Sonnet 5 / GPT-5.4 | ~$0.08 to $0.09 | ~$77 to $91 | Specialist use | Stronger reasoning for complex reviews; too costly as the default. |
| GPT-5.5 / Claude Opus 5.5 | ~$0.15 to $0.22 | ~$154 to $215 | Not needed | Premium models with no identified need for routine audits. |

"Tested" figures are measured from my real audit runs (average $0.0354 per audit). Other figures are my estimates using published pricing and the same workload; actual cost varies with call length and response size.

### My recommendation

- Compare Gemini 3 Flash, Claude Haiku 5.5 and GPT-5.4 Nano on the same set of human-scored calls.
- Pick the model that best agrees with human auditors.

### Watch-outs

- Confirm the model actually answering matches the one configured; my earlier tests showed a mismatch.
- Keep three vendors in place to avoid dependence on one.

### Key point

- Even the costliest option I tested is under 6 cents per audit.
- Accuracy, not cost, is the deciding factor.

TESTING & NEXT STEPS

# What Testing Taught Me and What I Need From Leadership

I found that audit quality depends as much on clean input as on the AI model

| WHAT I FOUND | WHAT I DID |
|---|---|
| **Mixed audio** made the AI confuse the analyst with the caller. | I now require separate audio channels and check them automatically. |
| **Misplaced hold periods** in test recordings gave wrong hold scores. | I now verify test recordings before use. |
| **Time-zone differences** between Genesys and ServiceNow broke ticket matching. | I standardised times across both systems. |
| **Removing ticket numbers** from transcripts weakened ticket matching. | I aligned redaction settings to the type of data being processed. |
| **Missing client setup** meant procedures could not be found. | I now check client coverage before testing. |
| **Test records that hinted at the answer** skewed results. | I rewrote the test data to look like real tickets. |

**Key insight:** several early "failures" were caused by how I prepared the test material, not by the audit logic. I have made automatic checks on input quality a required control.

### Decisions and support I need

- **Hosting:** approval to assess self-hosted Langflow with the Nebula team.
- **Governance:** Security, Privacy, Legal and EVP review, including an AI Impact Assessment.
- **Retention:** approval of how long audit results are kept.
- **Credential removal:** a decision on whether to switch it on.
- **Access:** release of the requested Genesys production credentials.

### My next validation step

- An experienced auditor scores a reference set of calls independently.
- I measure the AI results against those scores.
- This proves accuracy, guides my model choice, and is required before results are used for coaching or performance.

**My ask:** endorse the production hosting assessment and the governance review, so I can move the platform from prototype to a validated, approved audit tool.
